

Function of Optical Module Transmission

Overview

Optical modules are compact devices that convert electrical signals into optical signals and vice versa. They are used in fiber optic communication systems to transmit data over long distances with minimal loss and interference. The working principle of optical modules is illustrated in the diagram shown in the Optical Module Working Principle Diagram. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside. The optical module, known as Optical Transceiver in English, is a general term for various module categories, including optical receiver modules, optical transmitter modules, optical transceiver modules, and optical forwarding modules. Today, when we talk about optical modules, we usually mean. An optical module usually consists of an optical transmitting device (TOSA, including a laser), an optical receiving device (ROSA, including a photodetector), functional circuits, main control circuit board (PCBA), housing and optical (electrical) interface and other components.
