

# Mesh Networking with Port Aggregation Switches

## Overview

This article describes Link Aggregation and how to implement it on Open Mesh Switches. Link Aggregation is the process of combining multiple physical links (ports, in the case of switches) to form one logical link, for purposes of increasing total available bandwidth, performance. This aggregation can be achieved through various technologies, such as LACP (Link Aggregation Control Protocol) or EtherChannel, which provide protocols for load balancing and fault tolerance. The following list details the basic. Switch-to-Switch Aggregation: This is useful in scenarios where you need to interconnect multiple switches to increase the bandwidth available between them and ensure network redundancy. It helps in managing higher traffic loads between switches. Link aggregation is sometimes called by other names: The most common device combinations involve connecting a switch to another switch, a server, a network attached storage (NAS). Arista switches support Multi-Chassis Link Aggregation (MLAG) to logically aggregate ports across two switches.
