

Relay protection inverse time start

Overview

IDMT is an abbreviation for Inverse Definite Minimum Time. Essentially, an IDMT curve informs us how long a protective relay will wait before tripping when it discovers an overcurrent fault. The “Inverse” portion is that the larger the fault current, the quicker the relay will trip. Selective short-circuit protection can be achieved in different ways, such as: Time-graded protection Time- and current-graded protection A straightforward way of obtaining selective protection is to use time grading. Operating time of inverse time relays is reduced as fault current magnitude grows, in contrast to that of finite time elements (very flat at magnitude. Phase over-current protection is a common and widely used protection scheme that is implemented in high voltage and low voltage networks. As we are more familiar with settings based on how we set the electromechanical relays, this section describes the ways to set the SEPAM relay for phase. Inverse Time Relay Definition: An inverse time relay is defined as a relay where the operation time decreases as the actuating quantity increases.
