

What IC is used in optical modules

Overview

A photonic integrated circuit (PIC) or integrated optical circuit is a microchip containing two or more photonic components that form a functioning circuit. This technology detects, generates, transports, and processes light. It converts electrical signals to optical impulses for transmission over fiber and converts received light back into electrical signals, enabling high-speed networking in telecom, cloud, and data center. Photonic integrated circuits (PICs) use light (photons) to transmit information, whereas traditional integrated circuits use electricity (electrons), enabling faster signal propagation. Whether you are creating a 100-Gbps or 400-Gbps, small form-factor pluggable (SFP) module, SFP+ transceiver, XFP module, CFP, X2/XENPAK module. Electronics increasingly supplemented by optics with the introduction of optical communication systems (1980s) for long distance telecommunication (lasers, photodetectors, optical fiber, waveguides, optical amplifiers, etc. Unlike electronic ICs, PICs experience minimal energy loss and interference.
